

## Utility: nagdmc\_dsu

### Purpose

**nagdmc\_dsu** computes means and, optionally, standard deviations of data values using a single pass through the data.

### Declaration

```
#include <nagdmc.h>

void nagdmc_dsu(long rec1, long nvar, long nrec, long dblk, double data[],
               void (*dfun)(long, long, double [], char *, int *), char *comm,
               long chunksize, long iwts, double xbar[], double s[],
               double *wsum, long *nzw, int *info);
```

### Parameters

- |    |                                                                                                                                                                                                                                                                       |                           |
|----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| 1: | <b>rec1</b> – long                                                                                                                                                                                                                                                    | <i>Input</i>              |
|    | <i>On entry:</i> the index in the data of the first data record used in the analysis.                                                                                                                                                                                 |                           |
|    | <i>Constraint:</i> <b>rec1</b> $\geq 0$ .                                                                                                                                                                                                                             |                           |
| 2: | <b>nvar</b> – long                                                                                                                                                                                                                                                    | <i>Input</i>              |
|    | <i>On entry:</i> the number of variables in the data.                                                                                                                                                                                                                 |                           |
|    | <i>Constraint:</i> <b>nvar</b> $\geq 1$ .                                                                                                                                                                                                                             |                           |
| 3: | <b>nrec</b> – long                                                                                                                                                                                                                                                    | <i>Input</i>              |
|    | <i>On entry:</i> the number of consecutive records, beginning at <b>rec1</b> , used in the analysis.                                                                                                                                                                  |                           |
|    | <i>Constraint:</i> <b>nrec</b> $> 1$ .                                                                                                                                                                                                                                |                           |
| 4: | <b>dblk</b> – long                                                                                                                                                                                                                                                    | <i>Input</i>              |
|    | <i>On entry:</i> the total number of records in the data block.                                                                                                                                                                                                       |                           |
|    | <i>Constraint:</i> <b>dblk</b> $\geq$ <b>rec1</b> + <b>nrec</b> .                                                                                                                                                                                                     |                           |
| 5: | <b>data</b> [ <b>dblk</b> * <b>nvar</b> ] – double                                                                                                                                                                                                                    | <i>Input</i>              |
|    | <i>On entry:</i> the data values for the $j$ th variable (for $j = 0, 1, \dots, \mathbf{nvar} - 1$ ) are stored in <b>data</b> [ $i * \mathbf{nvar} + j$ ], for $i = 0, 1, \dots, \mathbf{dblk} - 1$ . When the data function is used, <b>data</b> is not referenced. |                           |
| 6: | <b>dfun</b> – function supplied by user                                                                                                                                                                                                                               | <i>External Procedure</i> |
|    | <i>On entry:</i> the pointer to a data function supplied by the user.                                                                                                                                                                                                 |                           |
|    | <i>Constraint:</i> if <b>dfun</b> is a valid pointer, <b>data</b> must be 0.                                                                                                                                                                                          |                           |
- The specification of **dfun** is:

<pre>void dfun(long irec, long chunksize, double x[], char *comm, int *ierr)</pre>		
1:	<b>irec</b> – long	<i>Input</i>
	<i>On entry:</i> the index in the data of the first record returned.	
2:	<b>chunksize</b> – long	<i>Input</i>
	<i>On entry:</i> the number of consecutive records returned.	
3:	<b>x</b> [ <b>chunksize</b> * <b>nvar</b> ] – double	<i>Output</i>
	<i>On exit:</i> data values for the $j$ th variable (for $j = 0, 1, \dots, \mathbf{nvar} - 1$ ) must be returned in <b>x</b> [ $i * \mathbf{nvar} + j$ ], for $i = 0, 1, \dots, \mathbf{chunksize} - 1$ .	
4:	<b>comm</b> – char *	<i>Input</i>
	<i>On entry:</i> a communication parameter allowing additional information to be passed to <b>dfun</b> . This parameter is passed ‘as is’ through the calling function.	

- |                                                                                                                                                                                 |                     |               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|---------------|
| 5:                                                                                                                                                                              | <b>ierr</b> – int * | <i>Output</i> |
| <i>On exit:</i> if the value pointed to by <b>ierr</b> on return is greater than 100, the NAG DMC function will terminate immediately and <b>info</b> will point to this value. |                     |               |
- 7: **comm** – char \* *Input*  
*On entry:* a communication parameter allowing additional information to be passed to **dfun**. This parameter is passed ‘as is’ through the calling function.
- 8: **chunksize** – long *Input*  
*On entry:* if the data function is used, the function inputs no more than **chunksize** data records at a time; otherwise **chunksize** is not referenced.  
*Constraint:* if **dfun**  $\neq$  0, **chunksize**  $\geq$  1.
- 9: **iwts** – long *Input*  
*On entry:* if **iwts** = –1, no weights are used; otherwise **iwts** is the index in **data** in which the weights are stored.  
*Constraints:*  $-1 \leq \mathbf{iwts} < \mathbf{nvar}$ ; **iwts**  $\neq$  **yvar**; and if **nxvar**  $>$  0, **iwts**  $\neq$  **xvar**[*i*], for  $i = 0, 1, \dots, \mathbf{nxvar} - 1$ .
- 10: **xbar**[**nvar**] – double *Output*  
*On exit:* the array of variable means; if **iwts**  $\geq$  0, the value **xbar**[**iwts**] will not be set.
- 11: **s**[**nvar**] – double *Output*  
*On exit:* if required, the standard deviations of variables; otherwise **s** must be set to 0. Note that if **iwts**  $\geq$  0, the value **s**[**iwts**] will not be set.
- 12: **wsum** – double \* *Output*  
*On exit:* if **iwts**  $\geq$  0, **wsum** gives the sum of the weights; otherwise its value equals **nrec**.
- 13: **nzw** – long \* *Output*  
*On exit:* the number of data records with positive weights (equals **nrec** if **iwts** = –1).
- 14: **info** – int \* *Output*  
*On exit:* **info** gives information on the success of the function call:  
     0: the function successfully completed its task.  
     *i*;  $i = 1, 2, 3, 4, 6, 8, 9$ : the specification of the *i*th formal parameter was incorrect.  
     53: there were not at least two data records with positive weight values.  
     99: the function failed to allocate enough memory.  
      $> 100$ : an error occurred in a function specified by the user.

## Notation

<b>nvar</b>	the number of variables, $m$ .
<b>nrec</b>	the number of data records, $n$ .
<b>iwts</b>	if <b>iwts</b> $\geq$ 0, <b>iwts</b> is the index in the data that defines the weights, $w_i$ , for $i = 1, 2, \dots, n$ .
<b>xbar</b>	the sample means, $\bar{x}_j$ , for $j = 1, 2, \dots, m$ .
<b>s</b>	the standard deviations, $s_j$ , for $j = 1, 2, \dots, m$ .

## Description

For  $n$  data records on  $m$  variables a one-pass update algorithm (West 1979) is used to compute the means and standard deviations of variables.

Let  $x_i$  be the  $i$ th data record, for  $i = 1, 2, \dots, n$ , which takes a value  $x_{ij}$  for the  $j$ th variable, for  $j = 1, 2, \dots, m$ . The mean value of the  $j$ th variable is given by,

$$\bar{x}_j = \frac{\sum_{i=1}^n w_i x_{ij}}{\sum_{i=1}^n w_i}, \quad j = 1, 2, \dots, m.$$

The standard deviation of the  $j$ th variable is given by,

$$s_j = \frac{\sum_{i=1}^n w_i (x_{ij} - \bar{x}_j)(x_{ij} - \bar{x}_j)}{\sum_{i=1}^n w_i - 1}, \quad j = 1, 2, \dots, m.$$
